

Interconnection of Obesity, Metabolic Health and COVID-19

According to new findings, obesity and cardiometabolic diseases not only trigger a more severe course of COVID-19, but the infection itself could promote the development of these conditions.

In a new article, authors from the German Center for Diabetes Research (DZD) highlight the interconnection of obesity and impaired metabolic health with the severity of COVID-19. They provide information about the independent relationships of obesity, disproportionate fat distribution and impaired metabolic health with the severity of COVID-19. They also discuss mechanisms for a complicated course of COVID-19 and how this disease may impact on the global obesity and cardiometabolic pandemics. Finally, the authors provide recommendations for prevention and treatment in clinical practice and in the public health sector to combat global pandemics.

The authors summarise and discuss data from large and well-performed studies that investigated independent relationships of obesity with the severity of COVID-19 to disentangle the contribution of obesity, visceral fatness and impaired metabolic health for the course of COVID-19. They found convincing evidence that obesity and overt diabetes, but also visceral obesity and even mild hyperglycaemia, represent important risk factors for the disease course and may have an additive effect on the severity of COVID-19.

The impact of the SARS-CoV-2 infection on organ function is also discussed, focusing on the cardiometabolically relevant tissues and organs as the vessel wall, heart, kidneys, liver, gut and pancreas. The article addresses both, the immediate damage of COVID-19 to the organs and the long-term effects of the disease, most probably boosting the development of obesity and cardiometabolic diseases. Thus, obesity and cardiometabolic diseases not only trigger a more severe course of COVID-19, but the SARS-CoV-2 infection also promotes the development of these conditions.

Obesity and cardiometabolic diseases not only trigger a more severe course of COVID-19, but the SARS-CoV-2 infection also promotes the development of these conditions

The authors further highlight how treatment of obesity and impaired cardiometabolic health helps to avert a severe COVID-19 in patients infected with SARS-CoV-2. In this respect health professionals and politicians should now, more than ever, promote the health benefits of physical activity and support efforts to implement programmes and policies to facilitate increased physical activity and to promote a healthy diet. This might not only be relevant to directly reduce the burden of COVID-19 related morbidity and mortality among those infected, but may also be important in the context of SARS-CoV-2 vaccination, where response should be carefully evaluated in patients with obesity and/or diabetes mellitus, because of a potentially reduced or shortened response.
